

ELECTROSURGERY WITH IMPROVED CONTROL
APPARATUS AND METHOD

Background of the Invention

Field of the Invention

This invention relates generally to electrosurgery and more
5 specifically to the efficient control of electrosurgical cutting coagulation cautery
and fulguration.

Discussion of Related Art

The mechanism of electrosurgery is well known in its capability to
10 perform exacting surgical cuts and to provide coagulation, cautery, fulguration and
other unique effects. In general, electrosurgery involves the discharge of high
voltage at a very high frequency, typically in the form of a spark or arc. However,
as with any electrical spark discharge, control is always an issue. Without
oversimplifying environment effects, it generally is well known that electricity
15 tends to follow the course of least resistance. Unfortunately this tendency works
against the need of a surgeon to have absolute control of an electrosurgical
discharge, for example when he is attempting to make a precise surgical incision
in very tight quarters, as is the case in laparoscopic procedures.

Failure to achieve this control can cause inadvertent discharge of
20 the electrosurgical spark to an undesirable location. For example, if a metal
grasper or clamp is holding a portion of tissue, the electrical spark may discharge

to the grasper or clamp rather than overcome a smaller gap to the target tissue. This inadvertent discharge is even more probable realizing that a small gap between target tissue and the electrode is important to achieve an optimal electrosurgical effect.

5 The designers of electrosurgical generators have designed complex high frequency wave forms and blends of such wave forms, as well as sophisticated feedback and patient monitoring systems to achieve the present level of safety and efficacy. However, there is always the potential for accidental discharge and ancillary damage, particularly when electricity is provided in an
10 open environment. In comparison, to electrical current flows in a wire, electrosurgical discharge by way of an arc has not been particularly controllable. Certainly, a device and method adapted to control and direct an arc of electrosurgical energy would be particularly beneficial.

 It is appreciated in U.S. Patent No. 5,509,916, that a laser can be
15 used to establish an ionized conductive pathway for electrosurgery. The laser ionizes the molecules of air along the laser beam, thereby establishing a path of least resistance leading to an operative site. An electrosurgical spark or arc will follow this path of least resistance, ultimately producing an electrosurgical effect at the operative site. Thus, the laser effectively establishes a means for
20 controlling the electrosurgical arc, thereby avoiding an inadvertent or misdirected discharge.

 While this system may work well in air, such a gas may neither be available nor desired in an electrosurgical environment. For example, lasing air

would not be available in a laparoscopic environment if carbon dioxide were used as an insufflation gas. Furthermore, complete ionization of (rather than mere excitation) environmental air by a laser may not maximize the efficiency of the laser in establishing a pathway of least resistance.

5

Summary of the Invention

In accordance with the present invention, a device and method is disclosed for initiating, directing, and maintaining an electrosurgical discharge in a highly controlled manner. A virtual wire is created which substantially avoids
10 inadvertent and misplaced discharge of the electrosurgical energy. In one aspect, the present invention provides for an environment of gas molecules to be merely excited by a low-power laser beam to create a well-defined path to a precise target. An electrosurgical generator is then provided with sufficient power to fully ionize the excited molecules, thereby creating a path of least
15 resistance to the operative site.

In a preferred embodiment, the device may use the ambient gas of a laparoscopic environment, namely carbon dioxide, and a low powered laser to direct and control an electrosurgical instrument discharge. In an alternate embodiment, the electrosurgical instrument may supply the environmental gas as
20 well as the laser beam. The gas stream and/or the laser beam may be scanned, pulsed, defocused, or otherwise varied to provide a variety of electrosurgical effects.

In order to maximize the efficiency of the system, the laser can be provided with power only sufficient to energize the atoms of the environmental gas. Once these energized atoms have established the pathway to the operative site, energy from the electrosurgical generator can be used to fully ionize the
5 excited molecules to define the path of least resistance.

The present invention can also be used in an environment where air is neither available nor desired. For example in laparoscopic surgery, the insufflation gas, such as carbon dioxide, can provide the environmental gas and can be lased to define the pathway.

10 Further efficiencies can be generated by providing a laser beam at a frequency depended upon the excitation frequency of the environmental gas. Thus, a carbon dioxide gas discharge laser can most efficiently be used to excite carbon dioxide molecules, for example, in a laparoscopic electrosurgical procedure.

15 In one aspect, the invention includes an electrosurgical apparatus which is adapted to perform electrosurgery at an operative site on a patient. The apparatus includes a source of shielding gas that provides gas molecules having properties for being energized at a particular frequency to an excited state. A first delivery apparatus is coupled to this source of gas and adapted to deliver the
20 gas molecules in the proximity with the operative site. A laser is adapted to produce a laser beam providing laser energy at a frequency equal to about an integer multiple of the particular frequency of the environmental gas, and at a power generally sufficient to excite the gas molecules. A second delivery

apparatus is coupled to the lasers to deliver the laser beam along a pathway leading toward the operative site. An electrosurgery generator provides electrosurgical power and is coupled by a third delivery apparatus which delivers the electrosurgical power along the pathway toward the operative site. A
5 handpiece including a housing and an elongate probe can be used for one or all of the first, second, and third delivery apparatus. The laser energy is provided in an amount generally insufficient to ionize the gas molecules along the pathway. However, the electrosurgical power is provided in an amount generally sufficient to ionize the gas molecules excited by the laser.

10 In another aspect of the invention, an electrosurgical method is used to perform electrosurgery at an operative site of a patient. The method includes the step of providing a source of environmental gas molecules having an excitation frequency. These molecules are moved into proximity with the operative site and energized with a laser beam having a frequency equal to
15 about an integer multiple of the excitation frequency of the environmental gas. The laser beam is controlled to provide power sufficient to excite the gas molecules along a pathway leading toward the operative site. Electrosurgical power is delivered along this pathway to the operative site to perform the electrosurgery on the patient. The pathway can be established by one or more
20 and the electrosurgical power can be provided in either a monopolar or bipolar configuration.

In another aspect, the invention includes a laparoscopic method for performing electrosurgery at an operative site in the abdomen of a patient. This

method includes the step of insufflating the abdomen with gas molecules having an excitation frequency, exciting the gas molecules with a laser beam having a fundamental frequency or a harmonic thereof equal to about the excitation frequency of the insufflation gas, and delivering electrosurgical energy along the pathway of excited molecules to perform the electrosurgical operation at the operative site. The laser beam can be moved relative to the patient to vary the size and shape of the pathway. Either or both the laser beam and the electrosurgery energy can be pulsed.

In a further aspect of the invention, an electrosurgical method is used to perform laparoscopic electrosurgery at an operative site in the abdominal cavity of a patient. The cavity is initially insufflated with a gas having an excitation frequency. This insufflation gas is then lased at a lasing frequency to form a pathway of excited gas molecules leading toward the operative site. Electrosurgical energy is directed along this pathway to produce an electrosurgical effect on the patient.

In another aspect of the invention, a catheter having a proximal end and a distal end is adapted to perform electrosurgery within a body conduit. The catheter includes an elongate shaft which delivers an environmental gas into the conduit. A laser apparatus includes a light fiber carried by the shaft and adapted to release laser energy into the environmental gas to excite gas molecules along the pathway. An electrosurgical apparatus includes an electrode carried by the shaft and adapted to release electrosurgical energy along the pathway to perform electrosurgery along the body conduit. A balloon can be carried by the shaft and

inflated with a gas which is controllably released through a hole in the wall of the balloon. This release provides the environmental gas which is lased to produce the pathway. An associated process includes the steps of inflating the balloon with an inflation gas, releasing a portion of the inflation gas from the balloon, 5 exciting molecules of the inflation gas with laser energy to produce a pathway, and introducing electrosurgical energy into the pathway to perform electrosurgery within the body conduit.

In still a further aspect of the invention, the laser which is used for exciting the gas molecules provides a laser beam which is generated from an 10 active medium having a discharge frequency. The active medium may be a gas or a crystal and may be tunable to vary the discharge frequency.

These and other features and advantages of the present invention will become more apparent with a description of preferred embodiments and reference to the associated drawings.

Description of Preferred Embodiments and

Best Mode of the Invention

A patient is illustrated in Figure 1 and designated generally by the
15 reference numeral 10. The patient 10 has an abdominal wall 12 which defines an interior abdominal cavity of 14. In this view, the patient 10 is disposed on an operating table 16 and is prepared for laparoscopic surgery which is performed through the abdominal wall 12 within the abdominal cavity 14.

A laparoscopic procedure is facilitated by a plurality of elongate
20 trocars 18, 21, and 23, which are inserted through the abdominal wall and into the abdominal cavity 14. Various instruments can be inserted into and removed from the trocars 18, 21, and 23 to facilitate a particular operative procedure within the abdominal cavity 14.

In Figure 1, the patient 10 is prepared for electrosurgery in a laparoscopic procedure. A laser 25 is provided and connected through an optical fiber 27 to a laser probe 30 extending through the trocar 21. In like manner, an electrosurgical generator 32 is provided in a monopolar configuration with a grounding plate 34 and an electrosurgery handpiece 36. The grounding plate 34 is connected to the generator 32 through a lead 38, and provides a large area of electrical contact with the patient 10. The handpiece 36 is connected to the generator through a lead 41 and can be inserted through the trocar 18 into the abdominal cavity 14. Other instruments useful in this procedure might include a laparoscope 43 which might typically be inserted through the trocar 23 to provide for illumination and visualization within the cavity 14.

This arrangement of trocars and instruments is best illustrated in the side elevation view of Figure 2. In this figure, the abdominal cavity 14 is illustrated to include various organs such as a stomach 45, kidneys 47, and bladder 50. In the illustrated procedure, electrosurgery is being performed at an operative site 52 on the stomach 45.

In accordance with a preferred method of the present invention, the abdominal cavity 14 is initially inflated or insufflated with a gas such as carbon dioxide. This insufflation distends the abdominal wall 12 thereby increasing the volume of the working area within the abdominal cavity 14. After the cavity 14 has been insufflated, the laser probe 30 can be inserted through the trocar 21 and activated to direct a laser beam 54 toward the operative site 52.

In a manner described in detail below, the laser beam 54 energizes the molecules of the insufflation gas to create a pathway 56 leading toward the operative site 52. Once this pathway 56 is established, the electrosurgical generator 32 can be activated to produce an electrosurgical potential between the handpiece 36 and the grounding pad 34. This potential will produce a spark or arc 58 which is intended to produce an electrosurgical effect at the operative site 52. Control of this spark or arc 58 is maintained by introducing the arc 58 in proximity to the pathway 56 of excited molecules.

In a preferred method, electrosurgical potential ionizes the excited molecules along the pathway 56 to create a path of least resistance leading toward the operative site 52. Following this pathway 56, now defined by ionized molecules, the arc 58 can create the desired electrosurgical effect at the operative site 52.

This procedure, including the steps of lasing the insufflation gas to excite molecules along a pathway, and then ionizing the excited molecules can best be understood on the atomic level. In Figure 3, an atom 61 is illustrated schematically to include a nucleus 63 and two electron orbits or shells 65 and 67. Two electrons 720 and 72 are normally present in the inner most or first shell 65 while four electrons 74 are typically present in the second shell 67, the outer most shell in this particular atom. The atoms associated with the various elements in the periodic table differ primarily in the makeup of the nucleus 63, as well as the number of shells, such as the shells 65, 70, and number of electrons, such as the electrons 70, 72 and 74.

Of particular interest to the present invention is the nature of the electrons 70, 72, 74, when they are exposed to an energy source, such as an electrical probe 76. Initially it is noted that in each of the shells 65 and 67, the associated electrons have different energy levels. These energy levels are
5 lowest at the inner shell 65 and highest at the outer shell 67.

In response to the electrical field produced by the electrode 76, the electrons, such as the electron 72, become energized. As the energy level of the electron 72 increases, it moves from the lower energy shell 65 to the higher energy shell 67 as shown by an arrow 78 in Figure 4A. As the electron 72 moves
10 outwardly, it leaves an electron void or hole 81 in the first shell 65.

Even in the continued presence of the electrical field and the electrode 76, the electron 72 in the outer shell 67 is unstable particularly with the electron hole 81 present in the lower energy shell 65. As a consequence, the electron 72 will tend to fall back into the inner shell 65 as illustrated by the arrow
15 83 in Figure 4b. As the electron 72 moves from a higher energy level in the shell 67 to a lower energy level in the shell 65, the difference in energy is released as a photon 85. For purposes of future discussion, note that for a particular atom, the photon released in this process has a known energy level equal to the product of its frequency (f) and its wavelength (λ).

20 In very basic terms, this describes the operation of a laser wherein the photons are collected and collimated into a laser beam such as the beam 54 (Figure 2). In this process it will be noted in particular that the energized electrons move between the shells 65, 67 of the atom 61. As a result, the

number of electrons associated with the atom does not change. The atom is merely excited, not ionized. This excited atom is designated in Figure 4A by the reference numeral 86.

If additional energy is applied to an already excited atom, as
5 illustrated in Figure 4C, the energy of the electron, such as the electron 72 may exceed that necessary to maintain it in the outer shell 67. Under these circumstances, the electron 72 may be separated from the atom 61, as a free electron 87. This leaves an ionized atom 88 in a charged state. Importantly, the free electrons which result from this ionization, change the properties of the
10 pathway 56 (Figure 2). What was heretofore merely a pathway of excited atoms is now a pathway of ionized atoms which for the first time offers a path of least resistance for the electrical arc (Figure 2).

Given the distinctions between an energized atom and an ionized atom, it can now be appreciated that the pathway 56 illustrated in Figure 2 and
15 Figure 5 can initially be established merely by the excited atoms 86. Although these excited atoms 86 will not produce a path of least resistance, they nevertheless establishes a pathway of atoms which have already reached an excited state. Under these circumstances, the electrosurgical handpiece 36 can provide the remaining energy necessary to ionize the excited molecules as
20 illustrated in Figure 4C. The resulting release of free electrons (shown by the arrow 87 in Figure 4C) makes the pathway 56 a path of least resistance for subsequent delivery of the arc 58 toward the operative site 52.

In the past, electrosurgery has been performed in open procedures using a laser to fully ionize air along a pathway leading to an operative site.

Relying on a laser to produce a fully ionized pathway of least resistance has necessarily required a very high magnitude of laser power. Now, in accordance

5 with this invention, the laser is only required to produce a pathway of excited atoms rather than a pathway of fully ionized atoms. Although the pathway 56 resulting from this laser application does not define a path of least resistance, nevertheless a path to the operative site is defined by the excited atoms 86.

These atoms are most susceptible to the further application of energy to create

10 ionized atoms 88 and free electrons 87, thereby resulting in an ionized pathway of least resistance.

It is of particular interest to the present invention to contemplate the amount of energy, and particularly the frequency of the energy, used to energize the atom 61. It has been noted that the amount of energy required to displace an

15 electron between atom shells varies with the particular atom involved. Thus, an atom of oxygen would require a different level of excitation energy than would an atom of carbon, for example. In addition, the amount of excitation power

required is reduced when it is applied at a frequency which is dependent upon the excitation frequency of a particular atom. Importantly, when the excitation

20 power is applied at a frequency dependent upon the excitation frequency of the atom, the amount of power required is reduced.

The excitation frequency in this case is the same as the frequency previously discussed with reference to the energy of the photon 85 (Figure 4B).

Energy applied at this excitation frequency, or a harmonic thereof, requires less power to create the excited atom, such as the atom 86. Thus, if the photon frequency of the laser 86 is chosen to be the fundamental frequency (or the harmonic thereof) of the excitation frequency associated with the environmental gas, the power required for excitation can be greatly reduced. The same power advantages can be achieved by choosing the laser 76 with a photon frequency equal to the excitation frequency or any integer multiple or divisor thereof.

Of course there are several types of lasers including gas discharge lasers as well as crystal and diode lasers. Each laser has its own photon frequency which can be chosen relative to the excitation frequency of the environmental gas being used. Of course the gas discharged lasers are easiest to contemplate with the present invention, as it is only necessary to choose the particular laser having a discharge gas which is the same as that of the environmental gas used in the electrosurgical process. In some cases, the environmental gas will dictate the choice of the laser, while in other cases, the laser will dictate the choice of the environmental gas.

In a laparoscopic surgery environment, carbon dioxide is most commonly used as an insufflation gas. This gas necessarily defines the environmental gas for an electrosurgical laparoscopic procedure. The best choice for a laser under these circumstances would be a carbon dioxide discharge laser. This laser would require the least power to create the pathway of excited atoms in an insufflated laparoscopic procedure using carbon dioxide as the insufflation gas.

Given the low power requirements for the laser 25 in the present invention, a preferred embodiment for the handpiece 36 might be that illustrated in Figure 7. In this case, the handpiece 36 includes a housing 90 communicating with an elongate probe 92. A gas cartridge 94 can be carried by the housing 90 and adapted to release gas molecules 96 into the housing 90 and through the probe 92. These molecules 96 would provide the environmental gas in those procedures not otherwise providing an insufflation gas. The laser 25 and associated batteries 98 could also be carried in the housing 90. Activation of the laser 25 through the optical fiber 27 would energize the atoms associated with the gas molecules 96 to create the energized pathway.

The handpiece 36 could be coupled through the lead 41 to the electrosurgical generator 32. The generator 32, in a monopolar configuration would also be coupled through the lead 38 to the groundplate 34 disposed between the patient 10 and the operating table 16. Activation of the electrosurgical generator 32 would produce the electrosurgical power necessary to ionize the atoms of excited gas in the pathway 56. As previously discussed, this would create the path of less resistance for subsequent electrosurgical arcing to the operative site 52 on the patient 10.

In a bipolar configuration, the handpiece 36 might be constructed as illustrated in Figure 8. In this embodiment, elements of structure similar to those previously discussed are designated with the same reference numeral followed by the lowercase letter "a." Thus, the handpiece 36 is shown with the probe 92a including the optical fiber 27a, and the gas molecules 96a are

energized by the laser beam 54a. In this bipolar embodiment, the probe 92a includes two electrodes 99 and 101 which are connected respectively to the leads 38a and 41a of the electrosurgical generator 32a. In this embodiment, the spark or arc 58a will jump between the electrodes 99 and 101 along the pathway
5 56 of energized free electrons 87a.

Another embodiment for the handpiece 36 is illustrated in Figure 9 wherein elements of structure similar to those previously disclosed on designated with the same reference followed by the lowercase letter "b." In this embodiment, the probe 92b includes the two electrodes 99b and 101b in a
10 bipolar configuration, with the electrode 101b provided with fiberoptic apertures 103. Operation of this embodiment is similar to that of Figure 8 in that the environmental gases can be carried through the probe 92b to the vicinity of the electrodes 98b and 101b. The laser 25b can be coupled through the optical fiber 27b to the fiber apertures 103 in order to excite the molecules of environmental
15 gas. Electrosurgical power can then be provided by the generator 32b and through the leads 38b and 41b to the electrodes 101b and 98b, respectively. This will produce the desired ionization of the excited atoms 86b and facilitate arcing along a controlled pathway between the electrodes 98b and 101b.

Figure 10 illustrates an embodiment of the handpiece 36 which is
20 adapted to function as a laser knife or scalpel. In this embodiment, elements of structure similar to those previously discussed will be designated with the same reference numerals followed by the lowercase letter "c." In Figure 10, the

handpiece 36 is illustrated to be completely self-contained and with powering both the laser 25c and the electrosurgery generator 32c.

In a procedure wherein the environmental gas is provided, for example by an insufflation gas, the laser 25c can initially be operated to energize the environmental gas molecules. In this case, the embodiment of Figure 10 provides for the laser beam 54c to be moveable through an aperture 105 to create the pathway 56c having an elongate and generally planar configuration. By energizing the electrosurgical generator 32c, the electrode 27c is activated to ionize the atoms in the pathway 56c. This facilitates the control led delivery of the electrosurgical spark or arc 58C along the planar pathway 56c.

A further embodiment of the invention is illustrated in the side elevation view of Figure 11 where elements of structure similar to those previously disclosed are designated with the same reference numeral followed by the lowercase letter "d." In Figure 11, the concept of the invention is embodied as a catheter 108 having a hub 110 and a catheter body 112 which extends to a distal end 114 along an axis 115. As best illustrated in the plan view of Figure 12, the electrosurgical lead 41b from the electrosurgical generator 32 (Figure 1), and the optical fiber 27d from the laser 25 (Figure 1), can be introduced into the hub 110 and extended through the catheter body 112. At the distal end 114, the electrosurgical lead 41d can be terminated in an electrode which in a preferred embodiment comprises a wire 116.

Also at the distal end 114, the optical fiber 27d can be provided with a distal tip having facets 118, or a refractive index coating selectively removed, to

permit the escape of light in a direction desired for the pathway 56d. In the illustrated embodiment, this direction is laterally of the axis 115 as shown by the pathway arrows 56d. In a particular embodiment wherein the environmental gas is already present, the wire electrode 116 and the optical fiber 27d may be all that is required to implement the concept of the present invention. Applying laser energy through the optical fiber 27d will excite the atoms of the environmental gas creating the pathway 56d in the direction dictated for example by the facets 118. Activating the wire electrode 116 will then cause electrosurgical energy to ionize the pathway 56d and create the desired electrosurgical effect.

A balloon 121 can also be provided at the distal end 114 of the catheter 108 to perform typical catheter balloon functions. In the illustrated embodiment, the balloon 121 has an inflatable wall 123 which includes portions that define a series of perforations 125. The balloon 121 may be centered on the catheter body 112 with the faceted distal tip 117 of the optical fiber 27d disposed within the balloon 121, for example near the axis 115. In this embodiment, the wire electrode 116 is preferably disposed along the outer surface of the balloon wall 123.

In operation, gas can be introduced through the hub 110 and along the catheter body 112 to inflate the balloon 121. As the balloon 121 is inflated, the inflation gas is permitted to leak through the perforations 125 into the environment surrounding the balloon 121. At this point, the laser 25 (Figure 1) can be activated to direct laser energy along the optical fiber 27d and to energize the atoms of the environmental gas along the pathway 56d. In the illustrated

embodiment, this pathway 56D will extend from within the balloon 121, through the inflation gas within the balloon 121, outwardly through the perforations 125, and through the environmental gas toward the operative site. Upon activation of the wire electrode 116, electrosurgical power will follow the pathway 56a to
5 create the electrosurgical effect.

The embodiment of a catheter, such as the catheter 108, can be a particular advantage where the electrosurgical effect is desired within a body conduit, such as the ureter. In such an embodiment, the addition of the balloon 121 can produce many synergistic effects. For example, the mere inflation of the
10 balloon can carry the electrode wire 116 into closer proximity to the wall of the conduit. And as noted, the gas used to inflate the wall 123 of the balloon 121 can also provide the environmental gas for the electrosurgical procedure. Appropriately perforated, the balloon 121 can be used to release the inflation gas into the environment and in a predetermined direction.

15 Another catheter embodiment is illustrated in the side view of Figure 14, the top view of Figure 15, and the end view of Figure 16. In these views, elements of structure similar to those previously described are designated with the same reference numeral followed by the lower case letter "e." Thus, the catheter 108e includes the hub 110e and the catheter body 112e. The balloon
20 121e is also included with its wall 123e and perforations 125e. As in the embodiment of Figure 11, the electrode wire 116e is disposed along the outer surface of the balloon wall 123. However, in this embodiment, the distal tip 117

of the optical fiber 127e is also carried on the outer surface of the balloon wall 123.

As in the previous embodiment, inflation gas can be introduced into the balloon 121e thereby expanding the wall 123 and carrying the electrode wire 116e and optical fiber distal tip 117 radially outwardly. As before, this inflation gas can be permitted to leak through the perforations 125e into the environment. When the laser fiber 127e is activated, the distal tip 117e will direct laser energy outwardly from the wall 123e of the balloon 121e in order to create the energized pathway 156e. As in the previous case, activation of the electrode wire 116e will follow this pathway 156e toward the operative site.

A further embodiment of the laser probe is illustrated in Figure 17 which provides a view similar to that of Figure 2. In Figure 17, elements of structure similar to those previously disclosed will be designated with the same reference numeral followed by the lower case letter "f." In this embodiment, the probe 30f has a distal end tip that is provided with a lens 130 at its distal end 114f. This lens 130 tends to diverge the laser beam 54f so that the operative site 52f is defined by an area, rather than a point as previously illustrated for the embodiment of Figure 2. With the laser beam 54f diverging, the pathway 56f of excited atoms also expands as it approaches the area of the operative site 52f. When the electrosurgical handpiece 36f is activated, the spark or arc 58f will be randomly directed within the area of the operative site 52f. This can be of particular advantage when the desired electrosurgical effect is to cauterize or coagulate over a wide area of the operative site 52f.

A further embodiment of the handpiece 36 is illustrated in Figures 18-20 wherein elements of structure similar to those previously discussed are designated with the same reference numeral followed by the lower case "g."

Thus the handpiece 36g includes the probe 92g containing at least the optical
5 fiber 27g and the electrosurgical electrode 101g. In the illustrated embodiment, the probe 92g also contains a second optical fiber 132. In this case, the two optical fibers 27g and 132 are distally terminated at lenses 134 and 136, respectively. The lens 134 associated with the fiber 27 causes the laser beam 54g to converge as illustrated. Similarly, the lens 136 associated with the fiber
10 132 causes a laser beam 138 to converge. Importantly, these two laser beams 54g and 138 can also be converged toward the operative site 52. This embodiment offers the advantage of providing increased laser power for development of the pathway 56g. Even with this increased power, the pathway 56g can be controlled to converge the electrosurgical energy toward the
15 operative site 52g.

It will be understood that many other modifications can be made to the various disclosed embodiments without departing from the spirit and scope of the concept. For example, various sizes of the surgical device are contemplated as well as various types of constructions and materials. It will also be apparent
20 that many modifications can be made to the configuration of parts as well as their interaction. For these reasons, the above description should not be construed as limiting the invention, but should be interpreted as merely exemplary of preferred

embodiments. Those skilled in the art will envision other modifications within the scope and spirit of the present invention as defined by the following claims
